Warranty and Assistance

The 4WFB120, 4WFB350, 4WFB1K 4 WIRE FULL BRIDGE TERMINAL INPUT MODULES are warranted by CAMPBELL SCIENTIFIC, INC. to be free from defects in materials and workmanship under normal use and service for twelve (12) months from date of shipment unless specified otherwise. Batteries have no warranty. CAMPBELL SCIENTIFIC, INC.'s obligation under this warranty is limited to repairing or replacing (at CAMPBELL SCIENTIFIC, INC.'s option) defective products. The customer shall assume all costs of removing, reinstalling, and shipping defective products to CAMPBELL SCIENTIFIC, INC. CAMPBELL SCIENTIFIC, INC. will return such products by surface carrier prepaid. This warranty shall not apply to any CAMPBELL SCIENTIFIC, INC. products which have been subjected to modification, misuse, neglect, accidents of nature, or shipping damage. This warranty is in lieu of all other warranties, expressed or implied, including warranties of merchantability or fitness for a particular purpose. CAMPBELL SCIENTIFIC, INC. is not liable for special, indirect, incidental, or consequential damages.

Products may not be returned without prior authorization. The following contact information is for US and International customers residing in countries served by Campbell Scientific, Inc. directly. Affiliate companies handle repairs for customers within their territories. Please visit www.campbellsci.com to determine which Campbell Scientific company serves your country. To obtain a Returned Materials Authorization (RMA), contact CAMPBELL SCIENTIFIC, INC., phone (435) 753-2342. After an applications engineer determines the nature of the problem, an RMA number will be issued. Please write this number clearly on the outside of the shipping container. CAMPBELL SCIENTIFIC'S shipping address is:

CAMPBELL SCIENTIFIC, INC.
RMA#____
815 West 1800 North
Logan, Utah 84321-1784

CAMPBELL SCIENTIFIC, INC. does not accept collect calls.

4WFB120, 4WFB350, 4WFB1K 4 Wire Full Bridge Terminal Input Modules

1. Function

Terminal input modules connect directly to the datalogger's input terminals to provide completion resistors for resistive bridge measurements, voltage dividers, and precision current shunts. The 4WFB120, 4WFB350, and 4WFB1K complete a full bridge for a strain gage or other sensor that acts as a single variable resistor. The difference between the three models is in the resistor that matches the nominal resistance of a 120 ohm, 350 ohm, or 1000 ohm quarter bridge strain gage.

3. Measurement Concepts

Measuring strain is measuring a change in length. Specifically, the unit strain ($\varepsilon$) is the change in length divided by the unstrained length ($\varepsilon = \Delta l / l$).

Strain is typically reported in microstrain ($\mu\varepsilon$); a microstrain is a change in length by one millionth of the length.

A metal foil strain gage is a resistive element that changes resistance as it is stretched or compressed. The strain gage is bonded to the object in which strain is measured. The gage factor, $GF$, is the ratio of the relative change in resistance for change in strain: $GF = \Delta R / R / \Delta l / l$. For example, a gage factor of 2 means that if the length changes by one micrometer per meter of length ($1\mu\varepsilon$), the resistance will change by two micro-ohms per ohm of resistance.

Because the actual change in resistance is so small, a full bridge configuration is used to give the maximum resolution. A "quarter bridge" strain gage is so named because the strain gage becomes one of the four resistors that make up a full bridge. The 4WFBxxx module provides the other three resistors (Figure 4-1). Quarter bridge strain gages are available in nominal unstrained resistances of 120, 350, and 1000 ohms. The 4WFB model must match the resistance of the gage (e.g., the 4WFB120 is used with a 120 ohm strain gage).

The resistance of an installed gage will differ from the nominal value. A zero measurement can be made with the gage installed. This zero measurement can be incorporated into the datalogger program; subsequent measurements can report strain relative to the zero.

Strain is calculated in terms of the result of the full bridge measurement. This result is the measured bridge output voltage divided by the bridge excitation voltage $V_{out} / V_{ex}$. (The actual result of the full bridge instruction is the millivolts output per volt of excitation, $1000 \cdot V_{out} / V_{ex}$.) The result of the zero measurement, $1000 \cdot V_{out0} / V_{ex}$ is stored and used to calculate future strain measurements. Strain is calculated from the change in the bridge measurement,

![Schematic](image_url)
\[ V_r = \left( \frac{V_{\text{out}}}{V_{\text{ex}}} \right) - \left( \frac{V_{\text{out0}}}{V_{\text{ex}}} \right) ; \]  

3.1.

\[ \varepsilon = \frac{4V_r}{GF(1 - 2V_r)} \]  

3.2.

The calculations are covered in more detail in section 6.

4. Wiring

![Diagram of wiring](FIGURE 4-1. Wiring for Example Programs)

Figure 4-1 illustrates the wiring of the strain gage to the 4WFB module and the wiring of the module to the datalogger. It is important that the gage be wired as shown with the wire from H connected at the gage, and that the leads to the L and G terminals be the same length, diameter, and wire type. With this configuration, changes in wire resistance due to temperature occur equally in both arms of the bridge with negligible effect on the output from the bridge.

5. Program Examples

The following examples for the CR10(X), 21X, CR7, and CR9000(X) all have a subroutine that measures the unstrained "zero" output of the strain gage. The examples calculate strain using equation 3.2 for a strain gage with a GF=2. These are just examples. Besides adding additional measurement instructions, the programs will probably need to have the scan and data storage intervals altered for actual applications. The instructions in the subroutine will also need to be modified for the actual gage factor.

This zeroing subroutine is called automatically when the program is first executed. The user can call the subroutine by setting Flag 1 low using the datalogger support software or the *6 mode with the keyboard display. The "zero" reading is then used during normal measurements for the strain calculations.
5.1 Edlog

Dataloggers that use Edlog include CR510, CR10(X), 21X, and CR7. The Edlog instruction that measures strain gages is Instruction 6 – Full Bridge.

The Input Locations assignments used in CR10(X), 21X, and CR7 Examples are listed in Table 5-1.

5.2 CRBasic

Dataloggers that use CRBasic include our CR800, CR850, CR1000, CR3000, CR5000, and CR9000(X). CRBasic uses the StrainCalc Instruction for calculating strain from the output of different full bridge configurations:

StrainCalc(Dest,Reps,Source,BrZero,BrConfig,GageFactor,PoissonRatio)

Source is the variable holding the current measurement, BrZero is the zero measurement; this instruction uses the results of the full bridge measurement instruction (multiplier=1, offset=0, mV/V) directly. The code for the Bridge Configuration used with the 4WFB module is -1. Enter the actual gage factor for GageFactor. Enter 0 for the Poisson ratio parameter which is not used with this bridge configuration.
5.2.1 CR9000(X)

This example program is slightly different in operation than the examples for the other dataloggers. Data are only output to data table STRAINS when the user sets Flag(1). Every measurement is output (rather than averages like in the other examples) while Flag(1) is high.

```
" Program name: STRAIN.DLD

Public Count, ZStrain, StMeas, Strain, Flag(8) 'Declare all variables as public

'Data Table STRAINS samples every measurement when user Sets Flag(1) High

DataTable(STRAINS,Flag(1),-1)
   DataInterval(0,0,0,100) 'Interval = Scan, 100 lapses
   Sample (1,Strain,IEEE4)
EndTable

'DataTable ZERO_1 stores the "zero" measurements

DataTable(ZERO_1,Count>99,100) 'Trigger on Count 100
   Average(1,ZStrain,IEEE4,0)
EndTable

'Subroutine to measure Zero, Called when user sets Flag(2)low

6. Calculation of Strain

Figure 6-1 is the diagram of the strain gage in the full bridge configuration provided by the terminal input module. The result of the datalogger's full bridge measurement when a multiplier of 1 and an offset of 0 is used is the measured bridge output in millivolts divided by the excitation in volts (1000 mV=1V):

\[
1000 \cdot \frac{V_{out}}{V_{in}} = 1000 \cdot \left( \frac{R_g}{R_3 + R_g} - \frac{R_2}{R_1 + R_2} \right) \]

The result is output in the units of millivolts output per volt of excitation because the output voltage is small relative to the excitation voltage; these units allow the result to be a larger number easier for the datalogger to display and store (see data format discussion in the datalogger manual). The output is a ratio because: 1) the datalogger's ratiometric measurement technique allows this ratio to be more accurate than the measurement of the output voltage (errors in the excitation and measured output cancel). 2) This ratio can be used directly in the calculation of strain.

When strain is calculated the direct ratio of the voltages (volts per volt not millivolts per volt) will be used:

\[
\frac{V_{out}}{V_{in}} = \frac{R_g}{R_3 + R_g} - \frac{R_2}{R_1 + R_2} \]

If the previous equation is taken as the result when the gage is unstrained, then when the gage is strained it will change resistance by \( \Delta R_g \). The equation for the bridge output is:

\[
\frac{V_{out}}{V_{in \, strained}} = \frac{R_g + \Delta R_g}{R_3 + R_g + \Delta R_g} - \frac{R_2}{R_1 + R_2} \]
Subtracting the unstrained (zero) result from the strained result gives $V_r$:

$$V_r = \left( \frac{V_{out}}{V_{in}} \right)_{\text{strained}} - \left( \frac{V_{out}}{V_{in}} \right)_{\text{unstrained}} = \frac{R_g + \Delta R_g}{R_3 + R_g + \Delta R_g} - \frac{R_g}{R_3 + R_g}$$

$$= \frac{R_3 \cdot \Delta R_g}{(R_3 + R_g + \Delta R_g) \cdot (R_3 + R_g)} \quad 6.6.$$  

The terminal input module is selected so that $R_3 = R_g$. Substituting $R_g$ for $R_3$:

$$V_r = \frac{R_g \cdot \Delta R_g}{(R_g + R_g + \Delta R_g) \cdot (R_g + R_g)} = \frac{R_g \cdot \Delta R_g}{4R_g^2 + 2R_g \Delta R_g} = \frac{\Delta R_g}{4R_g + 2 \Delta R_g} \quad 6.7.$$  

Solving for strain:

$$\left(4R_g + 2 \Delta R_g\right)V_r = \Delta R_g$$

$$4R_gV_r + 2 \Delta R_g V_r = \Delta R_g$$

$$4R_gV_r = \Delta R_g - 2 \Delta R_g V_r$$

$$4R_gV_r = \Delta R_g \left(1 - 2V_r\right)$$

$$\frac{4V_r}{1 - 2V_r} = \frac{\Delta R_g}{R_g} \quad 6.8.$$  

Strain is calculated by dividing equation 6.8 by the gage factor. The units are converted to microstrain by multiplying by $10^6 \mu S / S$.

$$\mu \varepsilon = \frac{4 \cdot 10^6 V_r}{GF(1 - 2V_r)} = \frac{10^6 \Delta R_g}{GF \cdot R_g} \quad 6.9.$$
